Executive Summary

Background

Colorado community corrections is a system of 35 halfway houses and programs across the state that provide both diversion from prison for offenders and a transition to the community for offenders leaving prison. Services are designed to promote productive reintegration of offenders back into the community.

This report focuses on client outcomes, in terms of discharges status and recidivism rates for each of the five community corrections modalities, including regular residential, therapeutic community, non-residential, residential dual-diagnosis treatment, and intensive residential treatment between January 2014 and December 2016. Information on offender characteristics, service needs assessment and treatment information, and termination reason (successful completion, new crime, escape/walk-away, and technical violation) was extracted from the Community Corrections Information and Billing (CCIB) system.

Rates of recidivism occurring within one year and two years post-discharge are also presented. These data were obtained from the Colorado Judicial Branch's information management system (ICON), which contains information concerning new misdemeanor or felony filings in county or district court. Information regarding filings in Denver County Court were not available and so are excluded from this analysis. Only cases successfully discharged and with the necessary “at risk” time¹ are included in the recidivism analyses. Thus, recidivism data are limited to clients discharged in calendar year 2014.

Findings

Residential Community Corrections

The purpose of the residential phase of community corrections is to provide offenders with the knowledge and skills necessary to be emotionally, cognitively, behaviorally and financially prepared for their reintegration into the community.

An analysis of 14,232 residential community corrections clients discharged between 2014 and 2016 found that the majority (55%) of residential community corrections clients were discharged from the program successfully. Clients participating in community corrections residential programs as a

¹ At-risk-time refers to the length of time an offender has been in the community and free to reoffend after termination from a community corrections program.

condition of parole were more likely to succeed than either transition or diversion clients (65% compared to 60% and 49%, respectively). However, clients participating in community corrections as a condition of parole were also more likely to recidivate. Within one year, 24% had received a new court filing, compared to 20% of diversion clients and 22% of transition clients.² Two years after discharge, 41% of these condition of parole clients had recidivated, compared to 37% of diversion and 36% of transition clients.³

Older clients in general were more likely to succeed in the program, and less likely to recidivate. Of those over 35, 67% succeeded, compared to 48% of those 35 and under. Male and female clients succeeded at almost identical rates (55% compared to 56%). Women, however, had lower recidivism rates. Women recidivated at rates of 15% after one year and 30% after two years, while the one- and two-year rates for men were 23% and 39%, respectively.

Education was directly correlated with successful termination. Less than half of the clients with less than a high school diploma or GED at the time of discharge successfully completed the program (44%), compared to 57% of those with a diploma or GED and 65% of those who had acquired some education beyond high school. Similarly, greater educational attainment was associated with a lower recidivism rate.

Clients with a mental health diagnosis were less likely to succeed in community corrections than those without: only 48% were successfully discharged compared to 61% for those without a diagnosis. However, having a mental health diagnosis had little effect on recidivism. The one- and two-year recidivism rates for those with and those without a diagnosis were virtually identical.

At intake, over half of both diversion and transition offenders were classified as high-risk on the LSI.⁴ These clients were least likely to succeed in the program and, if successfully terminated, more likely to recidivate. Of those assessed with a high level of risk at intake, 49% were successfully terminated, compared to 74% of low-risk clients. Recidivism rates for high-risk clients were 24% after one year and 42% after two years, compared to 8% at one year and 18% at two years for low-risk clients.

Providing a variety of services produced lower recidivism rates. Most clients did receive a combination of the service types examined (86%).⁵ Recidivism rates were slightly higher for those that were successfully discharged and did not receive any of these services than for clients who did receive some level of services. Recidivism rates for clients who received no services were 24% within one year and

² This difference is not statistically significant.

³ These differences are not statistically significant.

⁴ The Level of Supervision Inventory (LSI) is a 54-item assessment instrument that is administered in a semi-structured interview. The LSI provides a measure of risk for recidivism and profiles an offender's areas of need that contribute to his/her level of risk.

⁵ Services examined included those addressing substance abuse, employment and vocational needs, education, life skills, mental health, sex offense-specific treatment, domestic violence, anger management, and cognitive restructuring.

40% within two years. Those who did receive some combination of available services demonstrated one-year and two-year recidivism rates of 21% and 37%, respectively.

The impact of services received was particularly evident among transition offenders. One- and two-year recidivism rates were 17% and 28%, respectively, for transition clients who did receive some combination of the available services. These rates are significantly lower than the 23% one-year rate and the 45% two-year rate observed for those who did not receive any of the reported service types.

Therapeutic Communities (TCs)

A Therapeutic Community (TC) is residential in nature but has greater lengths of stay and is more structured. Typically, TCs have a 9-month minimum length of stay, and are designed for individuals with extensive criminal histories, antisocial behavior and multiple unsuccessful treatment attempts. These programs employ a therapeutic milieu and place high levels of responsibility on the individual participants for their treatment.

Between 2014 and 2016, 648 clients terminated from TCs. These programs had relatively high successful discharge rates (56%), comparable to those served in regular residential programs. Overall recidivism rates were much lower than those observed for regular residential clients, with 6% of successfully discharged TC clients having received a new filing within one year, compared to 21% of regular residential clients. Recidivism at two years was 20% for the TC client population, in contrast to 37% for regular residential clients.

These higher success rates and lower recidivism rates occurred in spite of the higher severity of the TC client population compared to the regular residential population. These clients had more extensive criminal histories, much more frequently had a mental health diagnosis in addition to significant addiction problems, and had much higher levels of risk and needs as measured by the LSI.

Younger clients appear to fare better in the therapeutic community environment than in regular residential, with 58% of clients under the age of 30 terminating successfully, compared to 44% for regular residential clients under 30. African American clients were successfully terminated in 63% of cases, in stark contrast to the 49% successful termination rate for African American clients in regular residential programs. Also in contrast to regular residential terminations, women were *less* often successfully discharged than men (47% compared to 58%).

Due to the intensive nature of TC programming, most participants successfully completing the program were likely to have had services addressing multiple areas of need (97% of clients, regardless of termination status, received a combination of the cataloged service types). Life skills training and employment/vocational services had the greatest association with successful termination. Over three-quarters (79%) of TC clients who received one or both of these service types were successful, substantially higher than the overall success rate of 56%.

Non-Residential Community Corrections

The non-residential phase of community corrections is designed to assist in the transition of stabilized residential *diversion* offenders back into the community, with a gradual decrease in supervision. Non-residential placement is not available to transition inmates or paroled clients. This analysis involved 2,359 non-residential community corrections clients who were discharged between 2014 and 2016.

Overall, non-residential clients were significantly more likely to successfully complete the program than residential diversion clients (64% compared to 49%). Recidivism rates were also much lower for these clients than for diversion clients successfully terminated from regular residential programs, at 16% within one year of discharge (compared to 20% for residential clients), and 28% within two years (compared to 37% for residential clients). This is not surprising as almost all non-residential clients have successfully completed a residential program immediately prior to admission to a non-residential program. Therefore, the overall profile of clients served in non-residential programs appears very similar to that of successful residential terminations. That is, they tended to be older, have lower risk scores, were more often female, Caucasian, had higher levels of education, and were more often employed than the overall residential population. In addition, the non-residential population had overall lower risk scores, and less frequently had a mental health diagnosis compared to the overall residential population.

Residential Dual Diagnosis Treatment (RDDT)

RDDT programs are professionally supervised therapeutic environments geared toward drug and alcohol abstinence, improved mental health and desistance from continued criminal conduct. Generally, the treatment program is aimed at offenders with both significant substance use and mental illness, including those whose previous treatment failures necessitate more intensive intervention.

Between 2014 and 2016, RDDT programs discharged 677 clients. Of all the community corrections modalities, these programs had the lowest successful discharge rate at 38%. It is notable, however, that those in the program as a condition of parole had a much higher success rate, at 61%. Diversion clients were successfully discharged in only 27% of cases, while transition offenders succeeded in 47% of cases.

Overall, one-year recidivism rates were slightly higher than those found for regular residential terminations (24% vs. 21%, respectively). However, two-year recidivism rates for RDDT clients were significantly higher than those for regular residential, at 45% for RDDT compared to 37% for regular residential.

While African American clients had the lowest success rates in regular residential programs, this group succeeded *more* often in RDDT than clients of other ethnic backgrounds. Over half (58%) of

African Americans served in RDDT successfully completed the program, compared to 49% of African Americans served in regular residential programs. Also in contrast to outcomes for regular residential programs, female clients were slightly *less* often successfully discharged, at 35% compared to 39% for men.

Intensive Residential Treatment (IRT)

Intensive residential treatment (IRT) is a 90-day correctional treatment program for individuals with serious substance use problems and is structured to accommodate persons with disorders related to prolonged substance use. Offenders participate in forty hours of therapeutic treatment per week.

The successful termination rates among the 2,199 IRT clients served between calendar years 2014 and 2016 were the highest found among all the modalities of community correction programs, at 77% overall. This is in spite of the chronic problems experienced by this population. However, recidivism rates were also the highest observed across all of the community corrections populations, with 28% recidivating within one year, and almost half (49%) within two years.

In contrast to the other modalities, African Americans were often successfully terminated, at 83%. African Americans also had the lowest recidivism rates among ethnic groups at 20% within one year and 47% at two years.⁶

Well over half (54%) of IRT clients had mental health needs. These clients were unsuccessfully discharged more frequently than those without such needs (28% versus 16%, respectively).

Additionally, a very large percentage of clients (87%) were assessed in the high spectrum of risk and needs on the Level of Supervision Inventory (LSI). While this condition had little bearing on successful termination rates, it was significantly correlated with recidivism risk. Of those assessed as high risk, 30% recidivated within one year, and 51% within two years. In comparison, recidivism rates for those assessed as low or medium risk were 19% within one year and 38% within two years.

⁶ The number of Asian American/Pacific Islander and Native American/Alaskan Native clients served was too low for results to be considered a reliable comparison.

Introduction

Colorado community corrections is a system of 35 separate residential and non-residential facilities across the state that provide both diversion from prison for offenders and transition to the community for offenders leaving prison. Six of these are operated by local governments, while the remainder are operated by private agencies. Services are designed to promote productive reintegration of offenders back into the community. Community corrections provide the following:

- services for offenders convicted of less severe felony offenses who are diverted from prison and sentenced to community corrections by the courts.
- services for offenders in transition between prison and parole.
- services for parolees referred by the Colorado Board of Parole or local parole offices as a condition of parole.
- short-term stabilization services for offenders on probation and parole.
- specialized treatment for offenders with a history of substance use and mental illness.

Participant data were extracted from the Community Corrections Information and Billing (CCIB) system. The CCIB system tracks an array of information related to offenders in the Colorado community corrections system, including current crime and criminal history, fiscal information (e.g., earnings, taxes, restitution and child support paid), standardized assessment outcomes, treatment services provided, and termination reasons.

Recidivism data were obtained from the Colorado Judicial Branch's information management system (ICON), which contains information concerning new misdemeanor or felony filings in county or district court. Information regarding filings in Denver County Court were not available and so are excluded from this analysis.

The DCJ's Office of Community Corrections develops an annual report with in-depth summaries of clients terminated from each of the program types outlined in this report.⁷ Therefore, this report will focus mainly on client outcomes, recidivism, and factors related to these.

Client outcome data are presented separately according to legal status, including diversion, transition, and condition of parole, and for all three populations combined. The first section of this report focuses on residential community corrections. This is followed with an analysis of clients in non-residential community corrections, residential dual diagnosis treatment (RDDT), Therapeutic Communities (TC) and intensive residential treatment (IRT).

⁷ Available at: <https://www.colorado.gov/pacific/dcj/community-corrections-reports-publications>.

Residential Community Corrections

The purpose of the residential phase of community corrections is to provide offenders with the knowledge and skills necessary to be emotionally, cognitively, behaviorally and financially prepared for their reintegration into the community. Residential programs strive to accomplish this rehabilitative task by a variety of means.

Through assessment-driven individual treatment plans, programs attempt to match offender risks and needs with the most appropriate treatment modality. Offenders are assisted in obtaining regular employment and encouraged to participate in educational and vocational services. Programs monitor the payment of restitution, court fines, court-ordered child support and useful community service requirements. Program staff carefully monitor offenders in the community to enhance offender accountability and to address public safety concerns.

Tables 1 through 9 provide detailed information regarding the profiles and termination status of 14,232 residential community corrections clients terminated between calendar years 2014 and 2016 (January 2014 and December 2016). Terminations for successful completion of the program, escape, technical violations and new crimes are included in this analysis, while terminations due to transfer to another program or other reasons are excluded. Also presented are one- and two-year recidivism rates for clients successfully terminated in 2014 only, allowing adequate time at risk for re-offense to occur.⁸

Program success and client characteristics

As shown in Table 1, the majority (55%) of residential community corrections clients were discharged successfully. Transition clients were more likely to be successful than diversion clients (60% compared to 49%, respectively).

Those participating in community corrections as a condition of parole succeeded at an even greater rate, at 65%.⁹ However, this group was also more likely to recidivate than the others. Within one year, 24% had received a new court filing, compared to 20% of diversion clients and 22% of transition clients. Two years after discharge, 41% of the condition of parole clients had recidivated, compared to 37% of diversion and 36% of transition clients.¹⁰

Older clients, in general, were more likely to succeed in the program, and less likely to recidivate. Of those over 35, 67% succeeded, compared to 48% of those 35 and under. Only 23% of those under 21 completed the program successfully.

⁸ The term "at risk" refers to the length of time an offender has been in the community and free to reoffend after termination from a community corrections program.

⁹ This difference is statistically significant at $p < .001$.

¹⁰ These differences are not statistically significant.

Similarly, older clients had lower recidivism rates. Those 35 and older had recidivism rates of 18% within one year of discharge, and 31% within two years. In comparison, those under 35 had recidivism rates of 24% at one year and 32% at two years.

Over half (55%) of residential community corrections clients were Caucasian. Both Caucasian clients and those of Asian/Pacific Islander descent were the most likely to succeed, at 55% and 62% respectively. African American clients were the least likely to be successful in residential community corrections, with just under half (49%) being successfully terminated. However, Hispanic clients were the most likely to recidivate. One- and two-year recidivism rates for non-Hispanic clients were 20% and 35%, respectively. In comparison, recidivism rates for Hispanic clients were 24% at one year and 42% at two years.

Female clients succeeded only slightly more often than men (56% compared to 55%). However, women demonstrated significantly lower recidivism rates, at 15% within one year and 30% within two years. Men, in comparison, demonstrated one- and two-year rates of 23% and 39%, respectively.

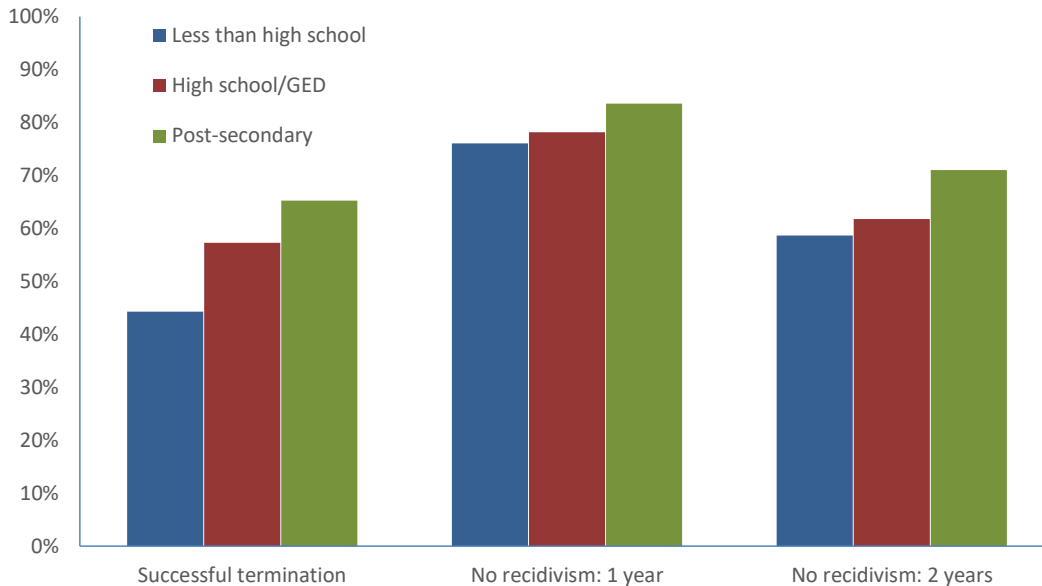

Clients who had previously been married both succeeded more often and recidivated less often than either single or currently married clients. Divorced, widowed or separated clients were successfully terminated in 62% of cases, compared to 54% for single or married clients. These previously married clients demonstrated recidivism rates of 18% at one year and 31% at two years, compared to 22% and 39% within one year and two years (respectively) for all other clients.

Table 2 displays educational attainment at both intake and termination. Ten percent of clients with no GED or high school diploma at intake did obtain one prior to termination.

Education was directly correlated with successful termination. This is unsurprising, as prior studies of Colorado's community corrections system have found having a high school diploma or GED to be highly predictive of program success.¹¹ Less than half of the clients with less than a high school diploma or GED at the time of discharge successfully completed the program (44%), compared to 57% of those with a diploma or GED and 65% of those who had acquired some education beyond high school. Similarly, greater educational attainment was associated with lower recidivism rates, as shown in Figure 1.

Figure 1. Educational attainment at termination and client outcomes

Employment

Because employment is a condition of retention in most programs, it is not surprising that employment has consistently been found to be linked to program success in community corrections.¹²

Table 3 outlines the employment status of clients both at intake and at termination. As shown, 89% of transition clients were unemployed or were considered unemployable. Since transition clients are in prison prior to entering community corrections, this is expected. However, the majority (70%) were employed full time when they left the program. Of these, 70% were successfully discharged.

Those placed in community corrections as a condition of parole are also most often unemployed or unemployable at intake (75%), as they have only recently been released from prison. However, only 56% were employed full time at termination. Of these, 78% were successfully terminated.

Diversion clients, on the other hand, are not necessarily incarcerated prior to intake (although it is possible they may have spent some time in jail). Nonetheless, over three-quarters (77%) were unemployed or unemployable. At the time of termination, 67% were employed full-time. Of these, 72% successfully completed the program.

While clients who were unemployed at termination demonstrated higher recidivism rates at one

¹² Hetz-Burrell, N. and English, K. (2006). *Community Corrections in Colorado: A study of program outcomes and recidivism, FY00-FY04*. Denver, CO: Colorado Department of Public Safety, Division of Criminal Justice, Office of Research and Statistics.

year than those who were either employed or unemployable due to disability (29% compared to 21%), this difference dissipated to some degree after 2 years, with a 40% recidivism rate for unemployable individuals compared to 37% for those who were employed or disabled.

Criminal history

Table 4 displays types of conviction crimes for which offenders were placed in community corrections. Property crimes were the most common type of conviction crime, involving 46% of diversion, 38% of transition, and 36% of the condition of parole clients.

Among diversion clients, those convicted of 'other' crime types¹³ were the most likely to succeed, but were also the most likely to recidivate. Violent offenders were the least likely to recidivate, with only 17% recidivating in the first year and 29% in the second year following discharge.

In the case of transition clients, drug offenders were the most likely to succeed in the program (64%), but violent offenders were the least likely to recidivate (31% within 2 years). However, among condition of parole clients, those convicted of violent crimes were most likely to succeed (70%) as well as the least likely to recidivate (34% within 2 years).

Table 4 also contains the criminal history scores of community corrections clients. The ORS Criminal History Score is an index reflecting the seriousness of an offender's criminal past. It is derived from a weighted combination of an offender's past convictions, placements and revocations. Collapsed scores range from 0 to 4, with 0 representing virtually no prior involvement in crime and 4 reflecting very serious offending histories. The Criminal History Score has been found to be statistically related to both program failure and program infractions.¹⁴

As expected, transition and paroled clients typically have more serious criminal histories than diversion clients. Over two-thirds of transition and condition of parole clients (70% and 68%, respectively) fell into the top category of seriousness. Just over half (53%) of diversion clients fell into this category. As expected, this group was also the most likely to recidivate, with 25% of clients overall recidivating within one year, and 41% within two years. In comparison, only 8% of those in the lowest category of criminal history seriousness recidivated within one year, and 18% within two years.

Client risk and needs

As shown in Table 5, a much larger proportion of paroled clients had a mental health diagnosis (41%) than did either transition or diversion clients (32% and 24%, respectively).¹⁵ Clients of all categories with such a diagnosis were less likely to succeed in community corrections than those without: only

¹³ 'Other' crimes include driving-related offenses, escape, habitual criminal, misdemeanors, delinquency of a minor, tampering, perjury, failure to register as a sex offender, contraband, unspecified inchoate offenses.

¹⁴ English, K. and Mande, M. (1991). *Community Corrections in Colorado: Why Do Some Succeed and Others Fail?* Denver, CO: Colorado Department of Public Safety, Division of Criminal Justice, Office of Research and Statistics; Harrison, L. (2010). *Fiscal Year 2008 Community Corrections Program Terminations: Client Needs, Services and Outcomes*. Denver, CO: Colorado Department of Public Safety, Division of Criminal Justice, Office of Research and Statistics.

¹⁵ No information concerning the specificity or severity of mental health diagnoses was available

48% were successfully discharged compared to 61% for those without a diagnosis.

However, having a mental health diagnosis had little effect on recidivism. The one- and two-year recidivism rates for those with and those without a diagnosis were virtually identical, with the one-year recidivism rate for both groups at 21%. The two-year recidivism rate for those with a mental health diagnosis was 38%, compared to 37% for those without.

Table 5 also shows the level of offender risk and need as determined by the Level of Supervision Inventory (LSI). This inventory is a 54-item assessment instrument that is administered in a semi-structured interview. The LSI provides a measure of risk for recidivism and profiles an offender's areas of need that contribute to his/her level of risk. Offenders score higher on the LSI as their risk of recidivism increases. The LSI is administered at intake and again at 6-month intervals to measure the degree of change in recidivism risk.

At intake, over half (56%) of all community corrections clients were classified as high-risk on the LSI. As expected, these clients were least likely to succeed in the program and more likely to recidivate after termination. After six months in the program, many of these high-risk individuals were re-classified at a lower risk level, as only a third were still considered high-risk.

Higher levels of risk at both intake and after 6 months in the program were clearly associated with unsuccessful discharge and recidivism rates. Of those assessed with low levels of risk at intake, 74% were successfully terminated, compared to 49% of high-risk clients. Recidivism rates for low-risk clients were 8% after one year and 18% after two years, compared to 24% at one year and 42% at two years for high-risk clients.

Standardized Offender Assessment and treatment matching

In community corrections, all offenders are screened and assessed upon intake with the Revised Standardized Offender Assessment (SOA-R). The purpose of the SOA-R process is to measure an offender's level of recidivism risk and criminogenic needs. The assessment process also measures the degree and severity of substance use and provides a treatment recommendation based on an offender's level of risk and severity of substance use.

Table 6 displays the substance abuse treatment recommendations for the client population, and the actual level of treatment clients were referred to. Most (81%) were assessed as requiring some form of outpatient treatment while few (12%) required either no treatment or alcohol and drug education only. Small percentages of the clients in residential community corrections were recommended for intensive residential treatment or a Therapeutic Community, as such clients were likely admitted to facilities offering these levels of treatment rather than to residential community corrections programs.

As shown in Table 7, approximately 82% of clients were actually referred to the level of treatment recommended by the SOA-R process. The degree to which treatment recommendations and treatment referrals matched made a slight difference in program success rates, with 57% of those referred to appropriate levels of treatment being successfully discharged compared to 54% of those

without an appropriate referral.

The degree to which treatment recommendations and treatment referrals correlated did appear to affect recidivism rates. Overall, 20% of those for whom treatment recommendations matched their treatment referral recidivated within one year, compared to 25% of those who did not have such a match. At two years, 36% of those with an appropriate treatment match recidivated, compared to 43% of those without.

Services received

Table 8 outlines the most common service types received, and program and recidivism outcomes for those receiving these services. It is difficult to determine the impact of services on these outcomes, as the needs and risk level of clients referred to available services types vary. For example, clients receiving sex offender-specific services were more frequently terminated for technical violations than were clients not receiving these services. However, only a small and very specific subset of clients would have been referred to this service type.

In combination, however, the provision of the variety of available services produced lower recidivism rates. Approximately 14% of all discharges did not receive any of the service types reported in Table 8. The successful discharge rate of these offenders was very low (37%). However, the proportion of those who did not receive any services and were discharged with an escape status was very high, at 35%. These clients likely had a short length of stay and did not have the opportunity to engage in services.

Recidivism rates for clients who did not receive any of the available services yet were successfully discharged were slightly higher than for clients who did receive some level of these services. Recidivism rates for clients who received no services were 24% within one year and 40% within two years. This compares to one-year and two-year recidivism rates of 21% and 37%, respectively, for clients who did receive some combination of available services.

The impact of services received was particularly evident among those placed in community corrections as a condition of parole. One- and two-year recidivism rates were 23% and 39%, respectively, for these clients who did receive some combination of the available services. These rates are significantly lower than the 28% one-year rate and particularly the 49% two-year rate observed for those who did not receive any of the reported service types.¹⁶

Length of stay

As shown in Table 9, successful diversion clients remained in the program for approximately 8.6 months, while successful transition clients had a slightly shorter stay at 7.6 months. Clients placed in residential community corrections as a condition of parole and successfully terminated had a much shorter length of stay, at 4.0 months. Those terminated for escape did so in a very short time, within

¹⁶ This difference was statistically significant at $p < .01$ for one-year recidivism rates and $p < .001$ for two-year recidivism rates. No significant difference was found in the case of diversion clients.

3 months of admission.

While length of stay appeared to have little association with future recidivism for either condition of parole or diversion clients, successfully discharged transition clients who remained recidivism-free stayed in community corrections approximately a month longer than those who did recidivate.¹⁷

¹⁷ While length of stay appeared to have little association with future recidivism for either condition of parole or diversion clients, successfully discharged transition clients who remained recidivism-free stayed in community corrections approximately a month longer than those who did recidivate

* Crime category refers to the most serious crime associated with the offender's current conviction. 'Other' crimes include driving-related offenses, escape, habitual criminal, misdemeanors, delinquency of a minor, tampering, perjury, failure to register as a sex offender, contraband, unspecified inchoate offenses.

** The ORS Criminal History Score is an index of an offender's past adjudications, convictions, placements and revocations. Collapsed scores range from 0 to 4, with 0 representing virtually no prior involvement in crime and 4 reflecting very serious offending histories

* No information concerning specific types of or the severity of mental health diagnoses was available.

**The Level of Supervision Inventory (LSI) is a risk and needs assessment administered at intake and again at 6-month intervals to measure the degree of change in recidivism risk. Higher scores indicate a higher need for services and supervision. LSI cut points were 1-18=low, 19-28=medium, and 24-54=high.

* All offenders are screened and assessed upon intake with the Standardized Offender Assessment Revised (SOA-R) process. The purpose of the SOA-R is to measure an offender's level of recidivism risk and criminogenic needs. The assessment process also detects and subsequently measures the severity of substance use and provides a treatment recommendation based on an offender's level of risk and severity of substance use.

Therapeutic Communities

Therapeutic Communities (TCs) are residential in nature but have greater lengths of stay and are more structured. Typically, TCs have a 9-month minimum length of stay, and are designed for individuals with extensive criminal histories, antisocial behavior and multiple unsuccessful treatment attempts. These programs employ a therapeutic milieu and place high levels of responsibility on the individual participants for their treatment.

Tables 10 through 16 provide detailed information regarding the profiles and termination status of 648 TC clients terminated between 2014 and 2016. Only terminations for successful completion of the program, escape, technical violations and new crimes are included, as those who were terminated due to transfer to another program or for other reasons are excluded. One- and two-year recidivism rates for clients successfully terminated in calendar year 2014 are also included in these tables.

Because all clients referred to Therapeutic Communities have been previously assessed as having significant substance abuse disorders, data concerning treatment levels recommended by the Revised Standardized Offender Assessment (SOA-R) and treatment matching are not presented.

Program success and client characteristics

As shown in Table 10, over half of TC clients were discharged successfully (56% overall). This is comparable to the successful discharge rate of regular residential clients, at 55%. Also similar to the regular residential population, the condition of parole population had the highest successful discharge rate at 61%, while transition offenders had the lowest at 49%.

Overall recidivism rates were much lower than those observed for regular residential clients, with 6% of successfully discharged TC clients having received a new filing within one year, compared to 21% of regular residential clients. Recidivism at two years was 20% for the TC client population, in contrast to 37% for regular residential clients.

These high success rates and lower recidivism rates occurred in spite of the higher severity of the TC client population compared to the regular residential population. These clients had more extensive criminal histories, more frequently had a mental health diagnosis in addition to significant addiction problems, and had higher levels of risk and need as measured by the LSI.

Younger clients appear to fare better in the therapeutic community environment than in regular residential, with 58% of clients under the age of 30 terminating successfully. This is in comparison to a successful termination rate of 44% for regular residential clients under 30. African American clients were successfully terminated in 63% of cases, in stark contrast to the 49% successful termination rate for African American clients in regular residential programs. Asian clients fared much more poorly in the TC

model, with only 40% successfully terminated, while 63% were successfully terminated from regular residential. The impacts of age and ethnicity on recidivism are difficult to ascertain, given the low numbers of clients in the recidivism sample within each of the sub-categories.

Also in contrast to regular residential terminations, women were *less* often successfully discharged than men (47% compared to 58%). Of those who successfully completed the program, women had lower recidivism rates at one year (3%, compared to 7% of men). However, after two years this difference equalized, with recidivism rates of 19% for women and 20% for men.

In keeping with regular residential terminations, education at termination was strongly associated with outcomes, as shown in Table 11. One-third (33%) of clients without a high school diploma or GED were successfully terminated, compared to 59% of those with such credentials. Recidivism rates for those with at least a high school diploma or GED were slightly lower than for those without (6% compared to 10% at one year, and 18% compared to 20% at two years).

Very few (6%) TC clients who were successfully terminated were unemployed. Therefore, any association between employment and recidivism based on the available data is unreliable (see Table 12).

Criminal history

As shown in Table 13, the largest proportion of TC clients were property offenders (45%). However, this group was the least often successfully discharged (50%). Drug offenders were the most frequently successfully discharged, at 65%. This group also had significantly lower recidivism rates than other offender types, at 3% after one year and 13% after two years.

Table 13 also displays the categorized criminal history scores for these TC terminations. As previously stated (see page 10), the criminal history score reflects the seriousness of an offender's criminal past, with collapsed scores ranging from 0 to 4. Zero represents virtually no prior involvement in the juvenile/criminal justice systems and 4 reflects very serious offending histories. As shown, few (30%) of TC clients had criminal history scores below the most serious level. As in the case of regular residential clients, lower criminal history scores appear to be associated both with successful termination and remaining recidivism-free.

Client risk and needs

A high proportion (39%) of TC clients entered treatment with a mental health diagnosis (see Table 14). These clients were less often successfully discharged than those without such a diagnosis. However, those who were successfully discharged had much lower recidivism rates. None of those with a mental health diagnosis had recidivated after one-year, compared to 9% of those without such a diagnosis. After two years, the recidivism rate for those with a mental health diagnosis was half of that for those

without (12% compared to 23%).

As previously stated, this population also had high needs as measured by the LSI. Almost all (98%) of TC clients were classified as high-risk at intake, with 2% considered medium-risk and none considered low-risk. This is unsurprising, as the TC model targets a high-risk clientele. After six months in the program, many of these high-risk individuals were re-classified at a lower risk level, such that the proportion considered low- or medium-risk increased to 17%.

While too few clients were considered low-risk at intake to draw any conclusions, it can be seen that those who lowered their risk level after 6 months in the program had better outcomes. Those who remained high-risk were successfully terminated in 76% of cases, while those who were re-assessed to be low- or medium-risk had an 88% success rate. However, this population of clients who reduced their risk category had slightly higher recidivism rates than those that remained in the high-risk category. Six percent of the high-risk group recidivated within one year, compared to 8%. The two year recidivism rate for the high-risk group was 19%, compared to 22% for the low and medium risk clients.

Length of stay and services received

Table 15 addresses the service and treatment types received. The greatest emphasis was placed on substance abuse treatment and mental health services, with 97% and 47% of clients receiving these two service types, respectively. These were followed by employment and vocational services (32%) and cognitive restructuring (27%). Little to no emphasis was placed on education, anger management, sex offender, and domestic violence treatment.

Life skills training and employment/vocational services had the greatest association with successful termination. Over three-quarters (79%) of TC clients who received one or both of these service types were successful, substantially higher than the overall success rate of 56%.

Due to the intensive nature of TC programming, most participants successfully completing the program were likely to have had services addressing multiple areas of need (97% of clients, regardless of termination status, received a combination of the cataloged service types). Therefore, it is unsurprising that the recidivism rates for clients receiving any of the service types cataloged were generally comparable to the overall recidivism rates of 6% at one year and 20% at two years (see Table 15). An exception to this was the recidivism rate among clients receiving employment or vocational services. These clients demonstrated lower recidivism rates, at 2% within one year and 15% at two years. Note the 33% recidivism rate reported for those with educational services cannot be considered reliable due to the very low number of successful clients who received that service (n=3).

Since the TC program modality is structured to be a long-term intensive course of treatment, the length of stay in treatment is much longer than that found for regular residential programs. As can be seen in Table 16, TC clients remained in the program for an average of 8.9 months, in contrast to 6 months for

regular residential clients. This discrepancy was more evident for successful terminations, as successful TC clients remained in treatment for over a year (12.3 months on average), compared to 7.6 months for regular residential clients.

Even though the average length of stay for clients remaining recidivism-free after one year was slightly longer than for those who recidivated at either one year or two years post-discharge, these differences were not statistically significant.

* Crime category refers to the most serious crime associated with the offender's current conviction. 'Other' crimes include driving-related offenses, escape, habitual criminal, misdemeanors, delinquency of a minor, tampering, perjury, failure to register as a sex offender, contraband, unspecified inchoate offenses.

** The ORS Criminal History Score is an index of an offender's past adjudications, convictions, placements and revocations. Collapsed scores range from 0 to 4, with 0 representing virtually no prior involvement in crime and 4 reflecting very serious offending histories.

* No information concerning specific types of or the severity of mental health diagnoses was available.

**The Level of Supervision Inventory (LSI) is a risk and needs assessment administered at intake and again at 6-month intervals to measure the degree of change in recidivism risk. Higher scores indicate a higher need for services and supervision. LSI cut points were 1-18=low, 19-28=medium, and 24-54=high.

Non-Residential Community Corrections

The non-residential phase of community corrections is designed to assist in the transition of stabilized residential *diversion* offenders back into the community with a gradual decrease in supervision (note that non-residential placement is not available to transition or condition of parole clients, who receive such supervision while on parole). Residential diversion offenders can be transferred to non-residential status if they have conducted themselves well in a highly structured residential setting. Such clients will have obtained a suitable independent living arrangement, managed their finances appropriately and will have progressed in treatment.

While in non-residential placement, offenders are required to meet with case management staff, retain employment, participate in mandatory treatment, honor their financial responsibilities and remain drug- and alcohol-free. Non-residential offenders are also subject to random monitoring of their living situations and employment verifications. Depending on supervision and treatment needs, an offender may be transferred back to a residential community corrections program for additional services. One of the added community safety benefits of non-residential placement is the ease with which an offender can be transferred back to residential placement until he or she is re-stabilized.

Tables 17 through 20 provide detailed information regarding the profiles and termination status of 2,359 non-residential community corrections clients terminated between calendar years 2014 and 2016. Only terminations for successful completion of the program, escape, technical violations and new crimes are included in this analysis, while those who were terminated due to transfer to another program or other reasons are excluded. One- and two-year recidivism rates for clients successfully terminated in 2014 are also included.

Since most non-residential clients have successfully completed a residential program immediately prior to admission to a non-residential program, the overall profile of these clients appears very similar to that of diversion clients successfully terminated from regular residential programs. That is, they tended to be slightly older, were more often female, Caucasian, had higher levels of education, and were more often employed than the overall residential population. In addition, the non-residential population had overall lower risk scores, and less frequently had a mental health diagnosis compared to the overall residential population.

Over two-thirds (64%) of this client population was successfully discharged, much higher than the 49% successful discharge rate for residential diversion clients. Recidivism rates were also much lower for these clients than for diversion clients successfully terminated from regular residential programs, at 16% within one year of discharge (compared to 20% for residential clients), and 28% within two years (compared to 37% for residential clients).¹⁸

¹⁸ Each of these differences was statistically significant at $p < .001$.

Successful clients tended to have a lengthy stay in treatment, at 8.9 months on average. Length of stay was very relevant in remaining recidivism-free: Those with no recidivism within one year had remained in treatment for an average of 16.0 months, compared to 9.4 months for those who did reoffend. Those who had not recidivated at 2 years had remained in the program for an average of 17.2 months, whereas those who did recidivate had spent an average of 8.0 months in non-residential treatment.¹⁹

¹⁹ Each of these differences was statistically significant at $p < .001$.

Residential Dual Diagnosis Treatment

The population of individuals in the justice system with co-occurring substance use and mental health disorders continues to increase. These persons require extensive psychiatric and mental health services as well as community based substance use treatment in order to manage their risk to public safety. Residential dual diagnosis treatment (RDDT) is a program within Colorado's community corrections system that is designed for these individuals so they may address co-occurring substance use and mental health disorders while building positive support systems and increasing their overall ability to function in the community. These programs are structured to accommodate persons in need of additional supervision and treatment services in order to successfully reintegrate into the community. Addressing co-occurring substance use and mental health disorders is the primary purpose of RDDT programs and offenders who are placed in these programs often have long histories of disruption as a result of these disorders.

RDDT programs are professionally supervised therapeutic environments geared toward drug and alcohol abstinence, improved mental health and desistence from continued criminal conduct. Generally, the treatment program is aimed at offenders with both significant substance use and mental illness, including those whose previous treatment failures necessitate more intensive intervention.

Tables 21 through 26 provide detailed information regarding the profiles and termination status of 677 RDDT clients terminated in between calendar years 2014 and 2016. Only terminations for successful completion of the program, escape, technical violations and new crimes are included. Those who were terminated due to transfer to another program or for other reasons are excluded. One- and two-year recidivism rates for clients successfully terminated in calendar year 2014 are also included in these tables.

Because addressing co-occurring substance use and mental health disorders is the primary purpose of RDDT programs, and because the content of the program is predetermined, data concerning mental health and services received are not included in the following tables and discussion.

Program success and client characteristics

Of all the community corrections modalities, these programs had the lowest successful discharge rate, at 38%. This is in comparison to the 55% overall success rate seen in regular residential programs. In addition, those clients who were successfully discharged from RDDT had the highest recidivism rates.

It is notable, however, that those in the program as a condition of parole had a much higher success rate, at 61%. This is very comparable to the successful termination rate of 65% for these clients in regular residential programs. Diversion clients were successfully discharged in only 27% of cases, while transition offenders succeeded in 47% of cases.

While one-year recidivism rates were only slightly higher than those found for regular residential terminations (24% vs. 21%, respectively), two-year recidivism rates for RDDT clients were significantly higher than those for regular residential, at 45% for RDDT compared to 37% for regular residential discharges. It is noteworthy that while the condition of parole population had quite high successful termination rates, this population also had much higher recidivism rates than diversion or transition clients. The one-year recidivism rate for the condition of parole clients was 35%, compared to 21% and 19% respectively for the diversion and transition populations. The two-year recidivism rate for this group was 53%, compared to 46% and 39% for the other two groups.

As in the case of regular residential clients, older transition clients succeeded more often than younger clients, with over 67% of clients over 35 succeeding, compared to 44% of those 35 and under. However, this pattern did not hold for diversion clients: practically identical proportions of those over 35 and those 35 and under succeeded (31% and 32%, respectively). In terms of recidivism, those 35 and younger had slightly higher one-year recidivism rates than those over 35 (26% vs. 23%), while the two groups had identical two-year recidivism rates (45%).

While African American clients had the lowest success rates in regular residential programs, this group succeeded *more* often in RDDT than clients of other ethnicities. However, this discrepancy was limited to diversion clients only. Among transition and condition of parole clients, Caucasians were most often successful, with success rates of 50% and 69%, respectively. In contrast, African Americans in these two groups succeeded at very low rates, at 33% for transition clients and 39% for condition of parole clients. The numbers of ethnic minorities included in the follow-up cohorts are too small to draw conclusions regarding ethnicity and recidivism.

In contrast to outcomes for regular residential programs, female clients were slightly *less* often successfully discharged, at 35% compared to 39% for men. However, those that were successfully terminated demonstrated lower recidivism rates than male clients, consistent with those discharged from regular residential programs.

Also consistent with regular residential clients, those who had previously been married succeeded more often than either single or married clients. However, marital status had no impact on recidivism rates.

Education

Table 22 displays educational attainment at both intake and termination. Little change in education status was observed between the two time points, which given the short length of stay and treatment focus of the program is not surprising.

As is the case with regular residential program clients, educational level was correlated with successful program completion. However, this did not hold with recidivism. Those with at least a high school diploma or GED demonstrated recidivism rates of 24% at one year, compared to 20% of those without. At two years, 47% of those with a diploma or GED recidivated, compared to 30% for those without.

Employment

Very few RDDT clients were employed at intake to the program: 80% were unemployed, and another 9% were considered unemployable due to disability (see table 23). By the time they were terminated, the proportion of unemployed clients fell to 47%. Only 15% of these unemployed clients were successfully terminated, compared to 58% of employed and disabled clients combined. However, employment status appeared to have no association with recidivism.

Criminal history

Table 24 displays types of conviction crimes for clients that were placed in an RTTD program. As was the case with other community corrections modalities, clients of all legal statuses were most often placed in community corrections for property offenses. While these clients, along with violent offenders were the least likely to succeed, they were also less likely to recidivate than either drug or 'other' offender types.

Table 24 also displays the criminal history scores of RDDT clients. The ORS Criminal History Score is an index reflecting the seriousness of an offender's criminal past and is described in greater detail earlier in this report (see page 10). Higher scores indicate more serious offending histories and have been found to be related to both program failure and program infractions.²⁰

However, unlike other community corrections modalities, criminal history appeared to have little association with success in RDDT programs. In fact, clients who were successfully discharged tended to have *higher* criminal history scores than those terminated unsuccessfully (including discharges for technical violations, escape and new crimes). Criminal history also appeared to be unrelated to

²⁰ English, K. and Mande, M. (1991). *Community Corrections in Colorado: Why Do Some Succeed and Others Fail?* Denver, CO: Colorado Department of Public Safety, Division of Criminal Justice, Office of Research and Statistics; Harrison, L. (2010). *Fiscal Year 2008 Community Corrections Program Terminations: Client Needs, Services and Outcomes*. Denver, CO: Colorado Department of Public Safety, Division of Criminal Justice, Office of Research and Statistics

recidivism rates, though the number of clients in the recidivism sample is too small to draw any conclusions.

Client risk and needs

Table 25 displays levels of offender risk and need as determined by the Level of Supervision Inventory (LSI). The LSI provides a measure of risk for recidivism and profiles an offender's areas of need that contribute to his/her level of risk. The LSI is administered at intake and re-administered after 6 months to measure the degree of change in recidivism risk.

Based on this assessment, RDDT clients have much higher levels of risk than regular residential program clients. Eighty-eight percent of all RDDT offenders were assessed as 'high risk', compared to 56% of regular residential clients. As expected, the highest risk clients had the lowest successful termination rate. However, these clients did not necessarily have the highest recidivism rates. The one-year recidivism rate overall was 22% for high-risk clients, compared to 29% for those considered medium risk. At two years, however, the high risk group was found to have a higher recidivism rate at 46%, compared to 41% for medium-risk clients (no low-risk clients were eligible for inclusion in the recidivism sample).

Average risk level did decrease while clients were in the program. After six months in the program, many of the high-risk individuals were re-classified at a lower risk level, with just over half (53%) still considered high-risk. The proportion of those assessed as low-risk increased from less than 1% at intake to 8% at termination.

Length of stay

As shown in Table 26, the average length of stay for clients successfully terminated was much longer than that of those unsuccessfully terminated. Individuals successfully terminated from RDDT programs remained in the program for approximately 7.5 months.

Length of stay was slightly associated remaining recidivism-free. Successfully discharged clients who did recidivate in either the first or second year post-discharge stayed in RDDT just under 7 months on average, compared to 7.6 months for those who did not recidivate.

Table 21. 2014-2016 Residential Dual Diagnosis Treatment (RDDT) terminations and recidivism rates (2014 successful terminations only): Legal status and demographics

* Crime category refers to the most serious crime associated with the offender's current conviction. 'Other' crimes include driving-related offenses, escape, habitual criminal, misdemeanors, delinquency of a minor, tampering, perjury, failure to register as a sex offender, contraband, unspecified inchoate offenses.

** The ORS Criminal History Score is an index of an offender's past adjudications, convictions, placements and revocations. Collapsed scores range from 0 to 4, with 0 representing virtually no prior involvement in crime and 4 reflecting very serious offending histories.

*The Level of Supervision Inventory (LSI) is a risk and needs assessment administered at intake and again at 6-month intervals to measure the degree of change in recidivism risk. Higher scores indicate a higher need for services and supervision. LSI cut points were 1-18=low, 19-28=medium, and 24-54=high.

Table 26. 2014-2016 Residential Dual Diagnosis Treatment (RDDT) terminations and recidivism rates (successful terminations 2014 only): average length of stay

Intensive Residential Treatment

Intensive Residential Treatment (IRT) is an inpatient correctional treatment program for individuals with serious substance abuse problems and is structured to accommodate persons with disorders related to prolonged substance use. Additionally, IRT programs treat individuals who lack a positive support system, experience denial and exhibit an inability to sustain independent functioning outside of a controlled environment.

IRT programs are 90 days in length, and offenders participate in forty hours of therapeutic treatment per week. The purpose of IRT is to provide a brief, intense treatment intervention. Treatment is aimed at increasing positive coping and relapse prevention skills and identifying negative thinking errors that have resulted in prior substance use and criminal behavior. Due to the intensive nature of IRT, participants do not leave the facility, seek employment, or address other community needs while in the program, as their focus is primarily on substance use and any mental health or physical health concerns that must be addressed in order for them to be successful in future community placements.

Tables 27 through 30 provide information regarding the profiles and termination status of 2,199 IRT clients terminated between calendar years 2014 and 2016. Only terminations for successful completion of the program, escape, technical violations and new crimes are included, as those who were terminated due to transfer to another program or for other reasons are excluded. One- and two-year recidivism rates for clients successfully terminated in 2014 are also included in these tables.

Because all clients referred to IRT have been previously assessed as having significant substance abuse disorders, and due to the nature of IRT programming, data concerning recommended treatment levels, services delivered, employment status, and education are not included in the following tables.

As shown in Table 27, successful termination rates among IRT clients served between calendar years 2014 and 2016 were the highest found among all the modalities of community correction programs, at 77% overall. This is in spite of the chronic problems experienced by this population. However, recidivism rates were also the highest observed across all of the community corrections populations, with 28% recidivating within one year, and almost half (49%) within two years.

Clients in community corrections as a condition of parole tend to have better success rates overall than diversion or transition clients. However, in the case of IRT clients, those on a condition of parole status have slightly lower success rates at 75%. Success rates for diversion clients was 77%, and for transition clients 82%.

Older clients, as in the case of the other community corrections modalities, were more likely to succeed in IRT. However, average age had no significant bearing on future recidivism (data not presented).

Most of the clients in IRT programs were Caucasian (61%) and were men (84%).²¹ In contrast to the other modalities, African Americans were often successfully terminated, at 83%. The Asian/Pacific Islander population had the highest successful termination rates (91%), though the number of such clients served was very low (n=11). African Americans also had the lowest recidivism rates among ethnic groups at 20% within one year and 47% at two years.²² It is notable that African American clients also had the highest success rates among RDDT terminations. It is possible that the short-term programming found with the RDDT and IRT modalities serve African Americans more effectively than longer-term programs.

In contrast to findings in previously reported,²³ women had higher successful termination rates than men (82% vs. 76%, respectively) and lower recidivism rates at 22% within one year and 38% within two years (compared to 30% at one year and 51% at two years for men).

Most clients were property or drug offenders (66% of the client population), with drug offenders having the highest overall success rates and the lowest recidivism rates (see Table 28). Drug offenders were terminated successfully in 80% of cases, compared to 76% for those convicted of other crime types. Drug offenders had one- and two-year recidivism rates of 21% and 43%, respectively, compared to 31% and 50% of other offender types.

Client risk and needs

Table 29 displays mental health diagnoses and LSI assessment scores for the IRT population. Well over half (54%) had mental health needs. These clients were unsuccessfully discharged more frequently than those without such needs (28% versus 16%, respectively).

A very large percentage of clients (87%) were assessed in the high spectrum of risk and needs on the Level of Supervision Inventory (LSI). However, this condition had little bearing on successful termination rates, with those on the low end of the spectrum successfully terminating in only 69% of cases, compared to 78% for those on the high end. Those assessed as medium risk succeeded most often, at 84%.

However, the LSI score was correlated with recidivism risk, with recidivism rates of 30% within one year and 51% within two years for those assessed as high risk. In comparison, recidivism rates for those assessed as low or medium risk were 19% within one year and 38% within two years.

²¹ The low percentage of females participating in IRT is determined by the limited number of treatment beds available to women.

²² The number of Asian American/Pacific Islander and Native American/Alaskan Native clients served was too low for results to be considered a reliable comparison.

²³ Among a cohort of IRT clients served in fiscal years 2012 and 2013, women were found to have lower successful termination rates than men and higher two-year recidivism rates. See: L. Harrison, et al (2013). *Community Corrections in Colorado: Program outcomes and recidivism, FY 2012-13*. Denver, CO: Colorado Department of Public Safety, Division of Criminal Justice, Office of Research and Statistics.

Length of stay

As shown in Table 30, the average length of stay for successful terminations was 89 days, very close to the 90 days specified for IRT programming. Clients unsuccessfully terminated tended to fail quickly, within 37 days on average.

Because the recidivism rates include only successfully terminated clients, all of whom would have remained in the program for approximately the required 90 days, no conclusions regarding recidivism and length of stay can be drawn.

*No information concerning specific types of or the severity of mental health diagnoses was available.

**The Level of Supervision Inventory (LSI) is a risk and needs assessment administered at intake and again at 6-month intervals to measure the degree of change in recidivism risk. Higher scores indicate a higher need for services and supervision. LSI cut points were 1-18=low, 19-28=medium, and 24-54=high.

Table 30. 2014-2016 Community corrections intensive residential treatment (IRT) terminations and recidivism rates (successful terminations 2014 only): length of stay

			Termination Reason			
	N	Mean	Success	Escape	New Crime	Technical Violation
Mean Length of Stay (days)						
Diversion	1066	76.5	88.4	22.5	50.3	42.9
Transition	496	80.5	89.1	40.0	29.3	42.8
Condition of Parole	637	75.3	89.1	22.6	45.0	38.1
Total	2199	77.0	88.7	26.1	41.8	41.4

			1 year recidivism		2 year recidivism	
	N		No	Yes	No	Yes
Mean Length of Stay (days)						
Diversion	182		87.3	87.5	87.2	87.5
Transition	129		88.1	87.9	88.6	87.4
Condition of Parole	173		89.2	88.2	88.8	88.9
Total	484		88.1	87.9	88.1	88.1
